

VehicleNet: Learning Robust Visual Representation for Vehicle Re-identification

Zhedong Zheng, Tao Ruan, Yunchao Wei, Yi Yang, Tao Mei

Abstract—One fundamental challenge of vehicle re-identification (re-id) is to learn robust and discriminative visual representation, given the significant intra-class vehicle variations across different camera views. As the existing vehicle datasets are limited in terms of training images and viewpoints, we propose to build a unique large-scale vehicle dataset (called VehicleNet) by harnessing four public vehicle datasets, and design a simple yet effective two-stage progressive approach to learning more robust visual representation from VehicleNet. The first stage of our approach is to learn the generic representation for all domains (*i.e.*, source vehicle datasets) by training with the conventional classification loss. This stage relaxes the full alignment between the training and testing domains, as it is agnostic to the target vehicle domain. The second stage is to fine-tune the trained model purely based on the target vehicle set, by minimizing the distribution discrepancy between our VehicleNet and any target domain. We discuss our proposed multi-source dataset VehicleNet and evaluate the effectiveness of the two-stage progressive representation learning through extensive experiments. We achieve the state-of-art accuracy of 86.07% mAP on the private test set of AICity Challenge, and competitive results on two other public vehicle re-id datasets, *i.e.*, VeRi-776 and VehicleID. We hope this new VehicleNet dataset and the learned robust representations can pave the way for vehicle re-id in the real-world environments.

Index Terms—Vehicle Re-identification, Image Representation, Convolutional Neural Networks.

I. INTRODUCTION

VEHICLE re-identification (re-id) is to spot the car of interest in different cameras and is usually viewed as a sub-task of image retrieval problem [1]. It could be applied to the public place for the traffic analysis, which facilitates the traffic jam management and the flow optimization [2]. Yet vehicle re-id remains challenging since it inherently contains multiple intra-class variants, such as viewpoints, illumination and occlusion. Thus, vehicle re-id system demands a robust and discriminative visual representation given that the realistic scenarios are diverse and complicated. Recent years, Convolutional Neural Network (CNN) has achieved the state-of-the-art performance in many computer vision tasks, including person re-id [3]–[5] and vehicle re-id [6]–[8], but CNN is data-hungry and prone to over-fitting small-scale datasets. Since the paucity of vehicle training images compromises the learning

of robust features, vehicle re-id for the small datasets turn into a challenging problem.

One straightforward approach is to annotate more training data and re-train the CNN-based model on the augmented dataset. However, it is usually unaffordable due to the annotation difficulty and the time cost. Considering that many vehicle datasets collected in lab environments are publicly available, an interesting problem arises: Can we leverage the public vehicle image datasets to learn the robust vehicle representation? Given the vehicle datasets are related and vehicles share the similar structure, more data from different sources could help the model to learn the common knowledge of vehicles. Inspired by the success of the large-scale dataset, *i.e.*, ImageNet [9], we collect a large-scale vehicle dataset, called VehicleNet, in this work.

Intuitively, we could utilize VehicleNet to learn the relevance between different vehicle re-id datasets. Then the robust features could be obtained by minimizing the objective function. However, different datasets are collected in different environments, and contains different biases. Some datasets, such as CompCar [10], are mostly collected in the car exhibitions, while other datasets, *e.g.*, City-Flow [2] and VeRi-776 [6], are collected in the real traffic scenarios. Thus, another scientific problem of how to leverage the multi-source vehicle dataset occurs. In several existing works, some researchers resort to transfer learning [11], which aims at transferring the useful knowledge from the labeled source domain to the unlabeled target domain and minimizing the discrepancy between the source domain and the target domain. Inspired by the spirit of transfer learning, in this work, we propose a simple two-stage progressive learning strategy to learn from VehicleNet and adapt the trained model to the realistic environment.

In a summary, to address the above-mentioned challenges, *i.e.*, the data limitation and the usage of multi-source dataset, we propose to build a large-scale dataset, called VehicleNet, via the public datasets and learn the common knowledge of the vehicle representation via two-stage progressive learning (see Figure 1). Specifically, instead of only using the original training dataset, we first collect free vehicle images from the web. Comparing with the training set of the CityFlow dataset, we scale up the number of training images from 26,803 to 434,440 as a new dataset called VehicleNet. We train the CNN-based model to identify different vehicles, and extract features. With the proposed two-stage progressive learning, the model is further fine-tuned to adapt to the target data distribution, yielding the performance boost. In the experiment, we show that it is feasible to train models with a combination of multiple datasets. When training the model

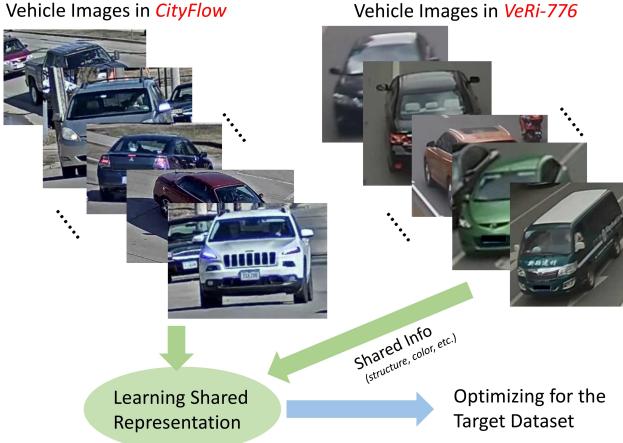

Fig. 1. The motivation of our vehicle re-identification method by leveraging public datasets. The common knowledge of discriminating different vehicles could be transferred to the final model.

with more samples, we observe a consistent performance boost, which is consistent with the observation in some recent works [1], [12], [13]. Without explicit vehicle part matching or attribute recognition, the CNN-based model learns the viewpoint-invariant feature by “seeing” more vehicles. Albeit simple, the proposed method achieves mAP 75.60% on the private testing set of CityFlow [2] without extra information. With the temporal and spatial annotation, our method further arrives the 86.07% mAP. The result surpasses the AICity Challenge champion, who also uses the temporal and spatial annotation. In a nutshell, our contributions are two-folds:

- To address the data limitation, we introduce one large-scale dataset, called VehicleNet, to borrow the strength of the public vehicle datasets, which facilitate the learning of robust vehicle features. In the experiment, we verify the feasibility and effectiveness of learning from VehicleNet.
- To leverage the multi-source vehicle images in VehicleNet, we propose a simple yet effective learning strategy, *i.e.*, the two-stage progressive learning approach. We discuss and analyze the effectiveness of the two-stage progressive learning approach. The proposed method has achieved competitive performance on the CityFlow benchmark as well as two public vehicle re-identification datasets, *i.e.*, VeRi-776 [6] and VehicleID [14].

The rest of this paper is organized as follows. Section II reviews and discusses the related works. In Section III, we illustrate the vehicle re-id dataset and the task definition, followed by the proposed two-stage progressive learning in Section IV. Extensive experiments and ablation studies are in Section V, and the conclusion is draw in Section VI.

II. RELATED WORK

A. Vehicle Re-identification

Vehicle re-identification (re-id) demands robust and discriminative image representation. The recent progress of vehicle re-identification has been due to two aspects: 1) the availability of the new vehicle datasets [2], [6], [14], [15] and 2) the

discriminative vehicle feature from deeply-learned models. Zapletal *et al.* [16] first collect a large-scale dataset with vehicle pairs and extract the color histograms and oriented gradient histograms feature to discriminate different cars. With recent advance in Convolutional Neural Network (CNN), Liu *et al.* [17] combine the CNN-based feature with the traditional hand-crafted features to obtain the robust feature. To take fully advantages of the fine-grained patterns, Wang *et al.* [8] first explore the vehicle structure and then extract the part-based CNN features according to the location of key points. Besides, Shen *et al.* [18] involve the temporal-spatial information into the model training as well as the inference process. Another line of works regards vehicle re-identification as a metric learning problem, and explore the objective functions to help the representation learning. Triplet loss has been widely studied in person re-id [19], [20], and also has achieved successes in the vehicle re-id [6]. Zhang *et al.* [21] further company the classification loss with triplet loss, which further improves the re-identification ability. Furthermore, Yan *et al.* [15] propose a multi-grain ranking loss to discriminate the appearance-similar cars. Besides, some works also show the attributes, *e.g.*, color, manufactories and wheel patterns, could help the model to learn the discriminative feature [2], [22], [23].

B. Dataset Augmentation

Many existing works focus on involving more samples to boost the training. One line of works leverage the generative model to synthesize more samples for training. Wu *et al.* [24] and Yue *et al.* [25] propose to transfer the image into different image styles, *e.g.*, weather conditions, and learn the robust feature for semantic segmentation. In a similar spirit, Zheng *et al.* [1], [26] utilize the Generative Adversarial Network (GAN) [27] to obtain lots of pedestrian images, and then involve the generated samples into training as an extra regularization term. Another line of works collects the real-world data from Internet to augment the original dataset. One of the pioneering work [12] is to collect large number of images via searching the keywords on the online engine, *i.e.*, Google. After removing the noisy data, the augmented dataset facilitate the model to achieve the state-of-the-art performance on several fine-grained datasets, *e.g.*, CUBird [28]. In a similar spirit, Zheng *et al.* [29] also exploit noisy photos of university buildings from Google, benefiting the model learning. In contrast with these existing works, we focus on leveraging the public datasets with different data biases to learn the common knowledge of vehicles given that the vehicle shares the similar structure.

C. Transfer Learning

Transfer learning is to propagate the knowledge of the source domain to the target domain [11]. On one hand, several recent works focus on the alignment between the source domain and the target domain, which intend to minimize the discrepancy of two domains. One of the pioneering works [30] is to apply the cyclegan [31] to transfer the image style to the target domain, and then train the model on the transferred data. In this way, the model could learn the similar patterns

of the target data. Besides the pixel-level alignment, some works [32]–[34] focus on aligning the network activation in the middle or high layers of the neural network. The discriminator is deployed to discriminate the learned feature of source domain from that of target domain, and the main target is to minimize the feature discrepancy via adversarial learning. On the other hand, some works deploy the pseudo label learning, yielding competitive results as well [35], [36]. The main idea is to make the model more confident to the prediction, which minimizes the information entropy. The pseudo label learning usually contains two steps. The first step is to train one model from scratch on the source domain and generate the pseudo label for the unlabeled data. The second step is to fine-tune the model and make the model adapt to the target data distribution via the pseudo label. Inspired by the existing works, we propose one simple yet effective two-stage progressive learning. We first train the model on the large-scale VehicleNet dataset and then finetune the model on the target dataset. The proposed method is also close to the traditional pre-training strategy, but the proposed method could converge quickly and yield competitive performance due to the related vehicle knowledge distilled in the model.

III. DATASET COLLECTION AND TASK DEFINITION

A. Dataset Analysis

We involve the four public datasets, *i.e.*, CityFlow [2], VeRi-776 [6], CompCar [10] and VehicleID [14] into training. It results in 434,440 training images of 31,805 classes as **VehicleNet**. Note that the four public datasets are collected in different places. There are no overlapping images with the validation set or the private test set. We plot the data distribution of all four datasets in Figure 2.

- **CityFlow** [2] is one of the largest vehicle re-id datasets. There are bounding boxes of 666 vehicle identities annotated. All images are collected from 40 cameras in a realistic scenario at USA City. We follow the official training/test protocol, which results in 36,935 training images of 333 classes and 19,342 testing images of other 333 classes. The training set is collected from 36 cameras, and test is collected from 23 cameras. There are 19 overlapping cameras. Official protocol does not provide a validation set. We therefore further split the training set into a validation set and a small training set. After the split, the training set contains 26,803 images of 255 classes, and the validation query set includes 463 images of the rest 78 classes. We deploy the all original training set as the gallery of the validation set.
- **VeRi-776** [6] contains 49,357 images of 776 vehicles from 20 cameras. The dataset is collected in the real traffic scenario, which is close to the setting of CityFlow. The author also provides the meta data, *e.g.*, the collected time and the location.
- **CompCar** [10] is designed for the fine-grained car recognition. It contains 136,726 images of 1,716 car models. The author provides the vehicle bounding boxes. By cropping and ignoring the invalid bounding boxes, we finally obtain 136,713 images for training. The same car

TABLE I
PUBLICLY AVAILABLE DATASETS FOR VEHICLE RE-IDENTIFICATION.[†]: WE VIEW THE VEHICLE MODEL PRODUCED IN DIFFERENT YEARS AS DIFFERENT CLASSES, WHICH LEADS TO MORE CLASSES. [‡]: THE DOWNLOADED IMAGE NUMBER IS SLIGHTLY DIFFERENT WITH THE REPORT NUMBER IN [14].

Datasets	# Cameras	# Images	# IDs
CityFlow [2]	40	56,277	666
VeRi-776 [6]	20	49,357	776
CompCar [10] [†]	n/a	136,713	4,701
VehicleID [14] [‡]	2	221,567	26,328
PKU-VD1 [15]	1	1,097,649	1,232
PKU-VD2 [15]	1	807,260	1,112
VehicleReID [37]	2	47,123	n/a
PKU-Vehicle [38]	n/a	10,000,000	n/a
StanfordCars [39]	n/a	16,185	196
VehicleNet	62	434,440	31,805

model made in different years may contain the color and shape difference. We, therefore, view the same car model produced in the different years as different classes, which results in 4,701 classes.

- **VehicleID** [14] consists 2211,567 images of 26,328 vehicles. The vehicle images are collected in two views, *i.e.*, frontal and rear views. Despite the limited viewpoints, the experiment shows that VehicleID also helps the viewpoint-invariant feature learning.
- **Other Datasets** We also review other public datasets of vehicle images in Table I. Some datasets contain limited images or views, while others lack ID annotations. For example, PKU-VD1 [15] only contains the front view of cars. Therefore, we do not use these datasets, which may potentially compromise the feature learning.

B. Task Definition

Vehicle re-identification aims to learn a projection function F , which maps the input image x to the discriminative representation $f_i = F(x_i)$. Usually, F is decided by minimizing the following optimization function on a set of training data $X = \{x_i\}_{i=1}^N$ with the annotated label $Y = \{y_i\}_{i=1}^N$:

$$\min \sum_{i=1}^N \text{loss}(WF(x_i), y_i) + \alpha \Omega(F), \quad (1)$$

where $\text{loss}(\cdot, \cdot)$ is the loss function, W is the weight of the classifier, $\Omega(F)$ is the regularization term, and α is the weight of the regularization.

Our goal is to leverage the augmented dataset for learning robust image representation given that the vehicle shares the common structure. The challenge is to build the vehicle representation which could fit the different data distribution among multiple datasets. Given $X^d = \{x_i^d\}_{i=1}^N$ with the annotated label $Y^d = \{y_i^d\}_{i=1,d=1}^N$, the objective could be formulated as:

$$\min \sum_{d=1}^D \sum_{i=1}^N \text{loss}(WF(x_i^d), y_i^d) + \alpha \Omega(F), \quad (2)$$

where D is the number of the augmented datasets. The loss demands F could be applied to not only the target dataset but

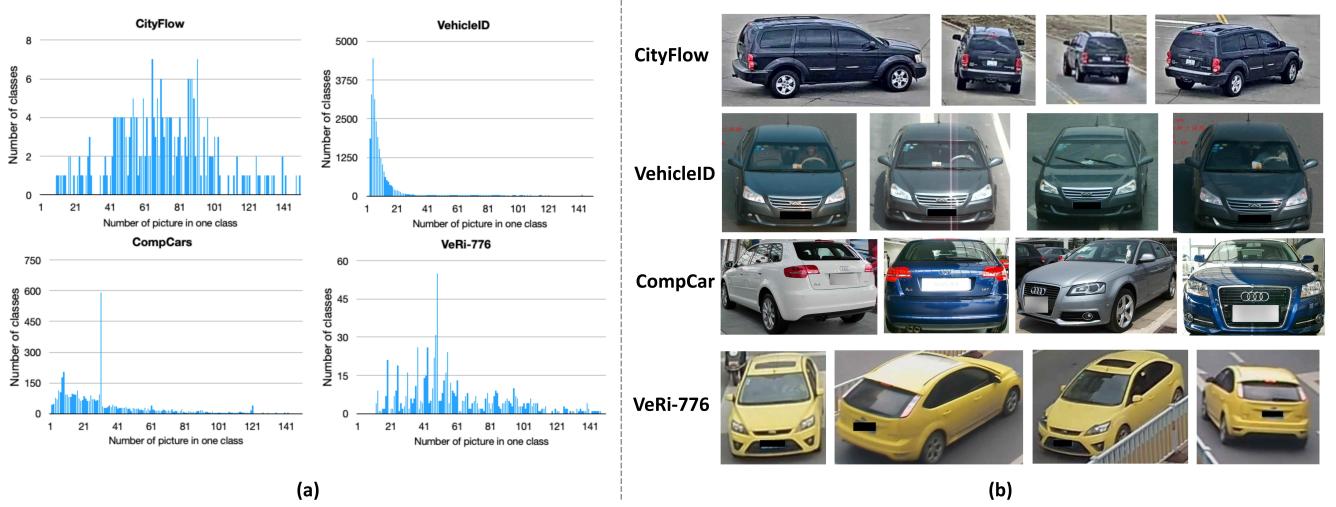

Fig. 2. (a) The image distribution per class in the vehicle re-id datasets, *e.g.*, CityFlow [2], VehicleID [14] , CompCar [10] and VeRi-776 [6]. We observe that the two largest datasets, *i.e.*, VehicleID and CompCars, suffer from the limited images per class. Note that there are only a few classes with more than 40 training images. (b) Here we also provide the image samples of the four datasets. The four datasets contain different visual biases, such as illumination conditions, collection places and viewpoints.

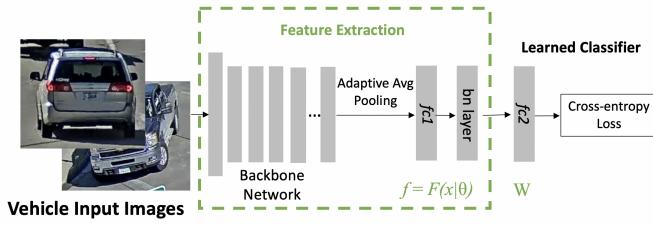

Fig. 3. Illustration of the model structure. We remove the original classifier of the ImageNet pre-trained model, add a new classifier and replace the average pooling with the adaptive average pooling layer.

also other datasets, yielding the good scalability. In terms of the regularization term $\Omega(F)$, we adopt the common practise of weight decay as the weight regularization, which prevents the value of weights from growing too large and over-fits the dataset.

IV. METHODOLOGY

We first illustrate the model structure in the Section IV-A. In the Section IV-B, we then introduce the proposed two-stage progressive learning method and discuss the advantage of the training strategy, followed by the description of the post-processing methods in the Section IV-C.

A. Model Structure

Feature Extractor. Following the common practise in re-identification problems [6], [40], we deploy the off-the-shelf Convolutional Neural Network (CNN) model pre-trained on the ImageNet dataset [41] as the backbone. Specifically, the proposed method is scalable and could be applied to different network backbones. We have trained and evaluated the state-of-the-art structures, including ResNet-50 [42], DenseNet-121 [43], SE-ResNeXt101 [44] and SENet-154 [44], in the

Section V. The classification layer of the pre-trained backbone model is removed, which is dedicated for image recognition on ImageNet. The original average pooling layer is replaced with the adaptive average pooling layer, and the adaptive average pooling layer outputs the mean of the input feature map in terms of the height and width channels. We add one fully-connected layer ‘fc1’ of 512 dimensions and one batch normalization layer to reduce the feature dimension, followed by a fully-connected layer ‘fc2’ to output the final classification prediction as shown in the Figure 3. The length of the classification prediction equals to the category number of the dataset. The cross-entropy loss is to penalize the wrong vehicle category prediction.

Feature Embedding. Vehicle re-identification is to spot the vehicle of interest from different cameras, which demands a robust representation to various visual variants, *e.g.*, viewpoints, illumination and resolution. Given the input image x , we intend to obtain the feature embedding $f = F(x|\theta)$. In this work, the CNN-based model contains the projection function F and one linear classifier. Specifically, we regard the ‘fc2’ as the conventional linear classifier with the learnable weight W , and the module before the final classifier as F with the learned parameter θ . The output of the batch normalization layer as f (see the green box in the Figure 3). When inference, we extract the feature embedding of query images and gallery images. The ranking list is generated according to the similarity with the query image. Given the query image, we deploy the cosine similarity, which could be formulated as $s(x_n, x_m) = \frac{f_n}{\|f_n\|_2} \times \frac{f_m}{\|f_m\|_2}$. The $\|\cdot\|_2$ denotes l^2 norm of the corresponding feature embedding. The large similarity value indicates that the two images are highly relevant.

B. Two-stage Progressive Learning

The proposed training strategy contains two stages. During the first stage, we train the CNN-based model on the Ve-

hicleNet dataset and learn the general representation of the vehicle images. In particular, we deploy the widely-adopted cross-entropy loss in the recognition tasks, and the model learns to identify the input vehicle images from different classes. The loss could be formulated as:

$$L_{ce} = \sum_{i=1}^N -p_i \log(q_i), \quad (3)$$

where p_i is the one-hot vector of the ground-truth label y_i . The one-hot vector $p_i(c) = 1$ if the index c equals to y_i , else $p_i(c) = 0$. q_i is the predicted category probability of the model, and $q_i = WF(x_i|\theta)$. Since we introduce the multi-source dataset, the cross-entropy loss could be modified to work with the multi-source data.

$$L_{ce} = \sum_{d=1}^D \sum_{i=1}^N -p_i^d \log(q_i^d), \quad (4)$$

where d denotes the index of the public datasets in the proposed VehicleNet. Specifically, $d = 1, 2, 3, 4$ denotes the four datasets in VehicleNet, *i.e.*, CityFlow [2], VehicleID [14], CompCar [10] and VeRi-776 [6], respectively. p_i^d is the one-hot vector of y_i^d , and $q_i^d = WF(x_i^d|\theta)$. Note that we treat all the dataset equally, and demand the model with good scalability to data of different datasets in VehicleNet.

In the first stage, we optimize the Equation 4 on all the training data of VehicleNet to learn the shared representation for vehicle images. The Stage-I model is agnostic to the target environment, hence the training domain and the target domain are not fully aligned. In the second stage, we take one more step to further fine-tune the model only upon the target dataset, *e.g.*, CityFlow [2], according to the Equation 3. In this way, the model is further optimized for the target environment. Since only one dataset is considered in the Stage-II and the number of vehicle category is decreased, in particular, the classifier is replaced with the new *fc2* layer with 333 classes from CityFlow. To preserve the learned knowledge, only the classification layer of the trained model is replaced. Although the new classifier is learned from scratch, attribute to the decent initial weights in the first stage, the model could converge quickly and meets the demand for quick domain adaptation. We, therefore, could stop the training at the early epoch. To summarize, we provide the training procedure of the proposed method in Algorithm 1.

Discussion: What are the advantages of the proposed two-stage progressive learning? First, the learned representation is more robust. In the Stage-I, we demand the model could output the discriminative representation for all of the data in the multi-source VehicleNet. The model is forced to learn the shared knowledge among the training vehicle images, which is similar to the pre-training practise in many re-ID works [5], [19]. Second, the representation is also more discriminative. The first stage contains 31,805 training classes during training. The auxiliary classes of other real vehicles could be viewed as “virtual class” as discussed in [45]. Here we provide one geometric interpretation in the Figure 4. After the convergence of Stage I, the cross-entropy loss pulls the data with the same label together, and pushes the data from different labels away

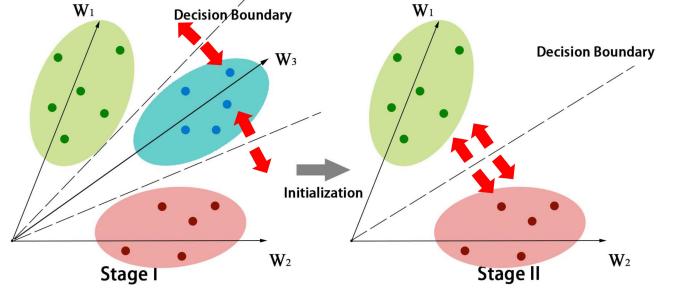

Fig. 4. Geometric Interpretation. Here we give a three-class sample to show our intuition. The cross-entropy loss pulls the samples with the same label together (close to either the relative weight W_1 , W_2 or W_3). In this way, the positive pair is closer than the negative pair, while the samples are far from the decision boundary. Stage I, therefore, leads to a decent weight initialization to be used in Stage II with a large margin from decision boundary, when we leave out the auxiliary class, *i.e.*, the third class with W_3 , from VehicleNet.

Algorithm 1 Training Procedure of the Proposed Method

Require: The multi-source VehicleNet dataset $X^d = \{x_i^d\}_{i=1}^D$; The corresponding label $Y^d = \{y_i^d\}_{i=1}^D$;

Require: The initialized model parameter θ ; The first stage iteration number T_1 and the second stage iteration number T_2 .

1: **for** $iteration = 1$ to T_1 **do**
2: Stage-I: Input x_t^d to $F(\cdot|\theta)$, extract the prediction of the classifier, and calculate the cross-entropy loss according to Equation 4:

$$L_{ce} = \sum_{d=1}^D \sum_{i=1}^N -p_i^d \log(q_i^d), \quad (5)$$

where p_i^d is the one-hot vector of y_i^d , and q_i^d is the predict probability. $q_i^d = WF(x_i^d|\theta)$, W is the final fully-connected layer, which could be viewed as a linear classifier. We update the θ and W during the training.

3: **end for**
4: **for** $iteration = 1$ to T_2 **do**
5: Stage-II: We further fine-tune the trained model only on the target dataset, *e.g.*, CityFlow. The classifier is replaced with a new one, since we have less classes. We assume that CityFlow is the first dataset ($d = 1$). Thus, we could update θ upon the cross-entropy loss according to Equation 3:

$$L_{ce} = \sum_{i=1}^N -p_i^1 \log(q_i^1). \quad (6)$$

where p_i^1 is the one-hot vector of y_i^1 of the CityFlow dataset, and q_i^1 is the predict probability. $q_i^1 = W'F(x_i^1|\theta)$. We note that W' is the new fully-connected layer, which is trained from scratch and different from W used in the Stage-I.

6: **end for**
7: **return** θ .

from each other on the either side of the decision boundary. In this manner, as shown in the Figure 4 (right), the first stage will provide better weight initialization for the subsequent fine-tuning on the target dataset. It is because the auxiliary classes expand the decision space and the data is much far from the new decision boundary, yielding discriminative features.

C. Post-processing

Furthermore, we also could apply several widely-adopted post-processing techniques during the inference stage as shown in Figure 5. For a fair comparison, we do not leverage such methods to comparing the results on the public datasets, but

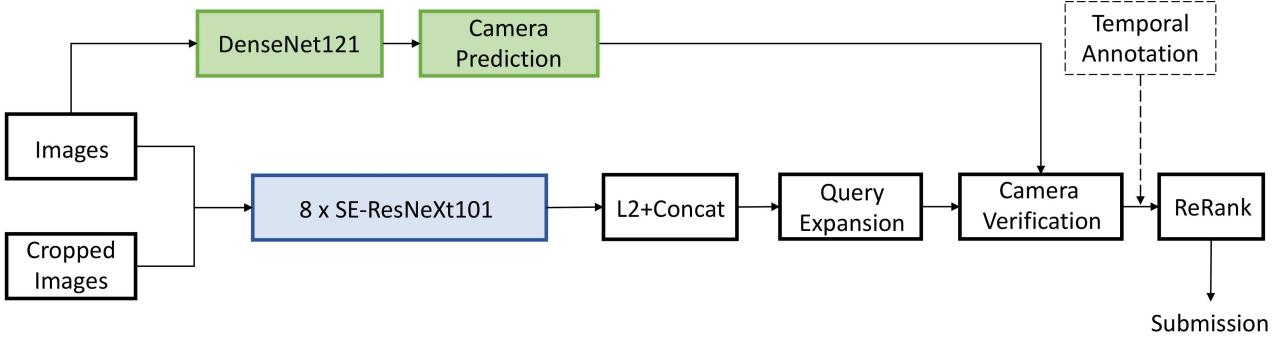

Fig. 5. The inference pipeline for AICity Challenge Competition. Given one input image and the corresponding cropped image via MaskRCNN [46], we extract features from the trained models, *i.e.*, $8 \times$ SE-ResNeXt101 [44]. We normalize and concatenate the features. Meanwhile, we extract the camera prediction from the camera-aware model, *i.e.*, the fine-tuned DenseNet121 [43]. Then query expansion and camera verification are applied. Finally, we utilize the re-ranking technique [47] to retrieve more positive samples. (This is the pipeline for the submission to the private test set on AICity Challenge 2019.)

apply them to the AICity Challenge Competition. Next we provide some brief illustrations of the motivation as well as the mechanism of these techniques.

Cropped Images. We notice that the vehicle datasets usually provide a relatively loose bounding box, which may introduce the background noise. Therefore, we re-detect the vehicle with the state-of-the-art MaskRCNN [46]. For the final result, the vehicle representation is averaged between the original images and cropped images, yielding more robust vehicle representations.

Model Ensemble. We adopt a straightforward late-fusion strategy, *i.e.*, concatenating the features [5]. Given the input image x_i , the embedding f_i^j denotes the extracted feature of x_i from the j -th trained model. The final pedestrian descriptor could be represented as: $f_i = [\frac{f_i^1}{\|f_i^1\|_2}, \frac{f_i^2}{\|f_i^2\|_2}, \dots, \frac{f_i^n}{\|f_i^n\|_2}]$. The $\|\cdot\|_2$ operator denotes l^2 -norm, and $[\cdot]$ denotes feature concatenation.

Query Expansion & Re-ranking. We adopt the unsupervised clustering method, *i.e.*, DBSCAN [48] to find the most similar samples. The query feature is updated to the mean feature of the other queries in the same cluster. Furthermore, we adopt the re-ranking method [47] to refine the final result, which takes the high-confidence candidate images into consideration. In this work, our method does not modify the re-ranking procedure. Instead, the proposed method obtains discriminative vehicle features that distill the knowledge from “seeing” various cars. With better features, re-ranking is more effective.

Camera Verification. We utilize the camera verification to further remove some hard-negative samples. When training, we train one extra CNN model, *i.e.*, DenseNet121 [43], to recognize the camera from which the photo is taken. When testing, we extract the camera-aware features from the trained model and then cluster these features. We applied the assumption that the query image and the target images are taken in different cameras. Given a query image, we remove the images of the same camera cluster from candidate images (gallery).

Temporal Annotation. One common assumption is that the cars that re-appear with long interval are different cars. Given the timestamp t of the query image, we filter out the image in the gallery with long interval τ . As a result, we only consider

TABLE II
THE RANK@1 (%) AND MAP (%) ACCURACY WITH DIFFERENT NUMBER OF TRAINING IMAGES. HERE WE REPORT THE RESULTS BASED ON THE VALIDATION SET WE SPLITTED. [†] NOTE THAT WE SPLIT A VALIDATION SET FROM THE TRAINING SET, WHICH LEADS TO LESS TRAINING DATA. WE APPLY SE-RESNEXT101 [44] AS THE BACKBONE MODEL.

Training Datasets	# Training Images	Performance	
		Rank@1 (%)	mAP (%)
CityFlow [2] [†]	26,803	73.65	37.65
CityFlow [2]+ VeVi-776 [6]	+49,357	79.48	43.47
CityFlow [2]+ CompCar [10]	+136,713	83.37	48.71
CityFlow [2]+ VehicleID [14]	+221,567	83.37	47.56
VehicleNet	434,440	88.77	57.35

the candidate images with the timestamp in $[t - \tau, t + \tau]$, which also could filter out lots of the hard-negative samples.

V. EXPERIMENT

We first illustrate the implementation details in Section V-A followed by the qualitative results in Section V-B. Furthermore, we provide the futher evaluation and discussion in Section V-C.

A. Implementation Details

For the two widely-adopted public datasets, *i.e.*, VeVi-776 and VehicleID, we follow the setting in [55], [56] to conduct a fair comparison. We adopt ResNet-50 [57] as the backbone network and the input images are resized to 256×256 . We apply the SGD optimizer with momentum of 0.9 and mini-batch size of 36. The weight decay is set to 0.0001 following the setting in [57]. The initial learning rate is set to 0.02 and is divided by a factor 10 at the 40-th epoch of the first stage and the 8-th epoch in the second stage. The total epochs of the first stage is 60 epochs, while the second-stage fine-tuning is trained with 12 epochs. When inference, we only apply the mean feature of the image flipped horizontally, without using other post-processing approaches.

For the new dataset, *i.e.*, CityFlow [2], we adopt one sophisticated model, *i.e.*, SE-ResNeXt101 [44] as the backbone to conduct the ablation study and report the performance. The

vehicle images are resized to 384×384 . Similarly, the first stage is trained with 60 epochs, and the second stage contains 12 epochs. When conducting inference on the validation set, we only apply the mean feature of the image flipped horizontally, without using other post-processing approaches. In contrast, to achieve the best results on the private test set of CityFlow, we apply all the post-processing methods mentioned in Section IV-C. To verify the effectiveness of the proposed dataset and the approach, we conduct the ablation study and report the results of the validation set in Section V-C.

Evaluation Metric. Following previous works [2], [54], we adopt two widely-used evaluation metrics, *i.e.*, Rank@K and mAP. Rank@K is the probability that the true-match image appears in the top-K of the ranking list. Given a ranking list, the average precision (AP) calculates the space under the recall-precision curve, while mAP is the mean of the average precision of all queries.

B. Qualitative Results

Effect of VehicleNet. To verify the effectiveness of the public vehicle data towards the model performance, we involve different vehicle datasets into training and report the results, respectively (see Table II). There are two primary points as follows: First, the model performance has been improved by involving the training data of one certain datasets, either VeRi-776, CompCar or VehicleID. For instance, the model trained on CityFlow + CompCar has achieved 83.37% Rank@1 and 48.71% mAP, which surpasses the baseline of 73.65% Rank@1 and 37.65% mAP. It shows that more training data from other public datasets indeed helps the model learning the robust representation of vehicle images. Second, we utilize the proposed large-scale VehicleNet to train the model, which contains all the training data of four public datasets. We notice that there are +15.12% Rank@1 improvement from 73.65% Rank@1 to 88.77% Rank@1, and +19.70% mAP increment from 37.65% mAP to 57.35% mAP. It shows that the proposed VehicleNet has successfully “borrowed” the strength from

TABLE IV
COMPETITION RESULTS OF AICITY VEHICLE RE-ID CHALLENGE ON THE PRIVATE TEST SET. OUR RESULTS ARE IN **BOLD**.

Team Name	Temporal Annotation	mAP(%)

Ours	✓	86.07

multiple datasets and help the model learning robust and discriminative features.

Comparison with the State-of-the-art. We mainly compare the performance with other methods on the test sets of two public vehicle re-id datasets, *i.e.*, VeRi-776 [6] and VehicleID [14] as well as AICity Challenge [54] private test set. The comparison results with other competitive methods are as follows:

- **VeRi-776 & VehicleID.** There are two lines of competitive methods. One line of works deploy the hand-crafted features [6], [49] or utilize the self-designed network [7], [8], [51]. In contrast, another line of works leverages the model pre-trained on ImageNet, yielding the superior performance [52]–[54], [56]. As shown in Table III, we first evaluate the proposed approach on the VeRi-776 dataset [6]. We leave out the VeRi-776 test set from the VehicleNet to fairly compare the performance, and we deploy the ResNet-50 [57] as backbone network, which is used by most compared methods. The proposed method has achieved 83.41% mAP and 96.78% Rank@1 accuracy, which is superior to the second best method, *i.e.*, Part-based model [56] (74.3% mAP and 94.3% Rank@1) by a large margin. Meanwhile, we observe a similar result on the VehicleID dataset [14] in all three settings (Small /Medium /Large). Small, Medium and Large setting denotes different gallery sizes of 800, 1600 and 2400, respectively. The proposed method also ar-

rives competitive results, *e.g.*, 83.64% Rank@1, 96.86% Rank@5, of the small gallery setting, 81.35% Rank@1, 93.61% Rank@5, of the medium gallery setting, and 79.46% Rank@1, 92.04% Rank@5, of the large gallery setting.

- **AICity Challenge.** For AICity Challenge Competition (on the private test set of CityFlow [2]), we adopt a slightly different training strategy, using the large input size as well as the model ensemble. The images are resized to 384×384 . We adopt the mini-batch SGD with the weight decay of 5e-4 and a momentum of 0.9. In the first stage, we decay the learning rate of 0.1 at the 40-th and 55-th epoch. We trained 32 models with different batchsizes and different learning rates. In the second stage, we fine-tune the models on the original dataset. We decay the learning rate of 0.1 at the 8-th epoch and stop training at the 12-th epoch. Finally, we select 8 best models on the validation set to extract the feature. When testing, we adopt the horizontal flipping and scale jittering, which resizes the image with the scale factors [1, 0.9, 0.8] to extract features. As a result, we arrive at 75.60% mAP on the private testing set. Without extra temporal annotations, our method has already achieved competitive results (see Table IV). With the help of extra annotation of temporal and spatial information (the top 3 team all used), we have achieved 86.07% mAP, which surpasses the champion of the AICity Vehicle Re-id Challenge 2019.

C. Further Evaluations and Discussion

Effect of Two-stage Progressive Learning. We compare the final results of the Stage I and the Stage II on the private test set of CityFlow (see Table V). We do not evaluate the performance on the validation set we splitted, since we utilize the all training images into fine-tuning. The model of Stage

TABLE VII

THE RANK@1 (%) AND MAP (%) ACCURACY WITH DIFFERENT BACKBONES ON THE CITYFLOW VALIDATION SET. THE BEST RESULTS ARE IN **BOLD**.

Backbones	ImageNet Top5(%)	Performance	
		Rank@1 (%)	mAP (%)
ResNet-50 [57]	92.98	77.97	43.65
DenseNet-121 [43]	92.14	83.15	47.17
SE-ResNeXt101 [44]	95.04	83.37	48.71
SENet-154 [44]	95.53	81.43	45.14

TABLE VIII

THE RANK@1(%) AND MAP(%) ACCURACY ON THE CITYFLOW VALIDATION SET WITH TWO DIFFERENT SAMPLING METHODS. HERE WE USE THE RESNET-50 BACKBONE.

Backbones	Performance	
	Rank@1(%)	mAP(%)
Naive Sampling	77.97	43.65
Balanced Sampling	76.03	40.09

II has arrived 87.45% Rank@1 and 75.60% mAP accuracy, which has significantly surpassed the one of Stage I +7.39% mAP and +4.75% Rank@1. It verifies the effectiveness of the two-stage learning. In the Stage I, the target training set, *i.e.*, CityFlow, only occupy 6% of VehicleNet. The learned model, therefore, is sub-optimal for the target environment. To further optimize the model for CityFlow, the second stage fine-tuning helps to minor the gap between VehicleNet and the target training set, yielding better performance. Besides, we also observe similar results on the other two datasets, *i.e.*, VeRi-776 and VehicleID. As shown in the last two row of Table III, the Stage-II fine-tuning could further boost the performance. For instance, the proposed method has achieved +2.50% mAP and +0.83% Rank@1 improvement on the VeRi-776 dataset.

Effect of Post-processing. Here we provide the ablation study of different post-processing techniques on the validation set of CityFlow (see Table VI). When applying the augmentation with cropped image, model ensemble, query expansion, camera verification and re-ranking, the performance gradually increases, which verifies the effectiveness of the post-processing methods. We also apply the similar policy to the final result on the private test set of AICity Challenge.

Effect of Different Backbones. We observe that different backbones may lead to different results. As shown in Table VII, SE-ResNeXt101 [44] arrives the best performance with 83.37 Rank@1 and 48.71% mAP on the validation set of the CityFlow dataset. We speculate that it is tricky to optimize some large-scale neural networks due to the problem of gradient vanishing. For instance, we do not achieve a better result (45.14% mAP) with SENet-154 [44], which preforms better than SE-ResNeXt101 [44] on ImageNet [9]. We hope this observation could help the further study of the model backbone selection in terms of the re-identification task.

Effect of Sampling Policy. Since we introduce more training data in the first stage, the data sampling policy has a large impact on the final result. We compare two different sampling policy. The naive method is to sample every image once in

Fig. 6. Qualitative image search results using the vehicle query images from the CityFlow dataset. We select the four query images from different viewpoints, *i.e.*, the front view, the overhead view, the rear view and the side view. The results are sorted from left to right according to the similarity score. The true-matches are in green, when the false-matches are in red.

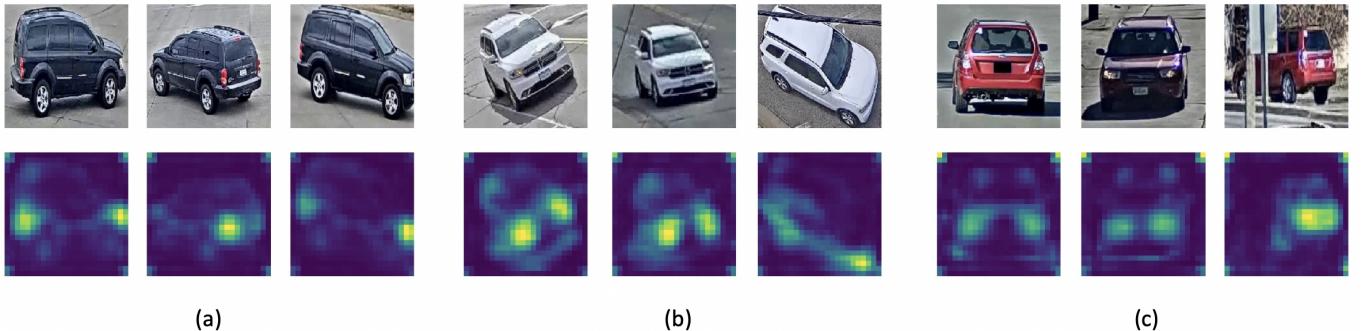

Fig. 7. Visualization of the activation heatmap in the learned model on VehicleNet. The vehicle images in every subfigure (a)-(c) are from the same vehicle ID. Noted that there do exist strong response values at the regions containing discriminative details, such as headlights and tire types.

every epoch. Another method is called balanced sampling policy. The balanced sampling is to sample the images of different class with equal possibility. As shown in Table VIII, the balanced sampling harms the result. We speculate that the long-tailed data distribution (see Figure 2) makes the balanced sampling have more chance to select the same image in the classes with fewer images. Thus the model is prone to over-fit the class with limited samples, which compromise the final performance. Therefore, we adopt the naive data sampling policy.

Visualization of Vehicle Re-id Results. As shown in Figure 6, we provide the qualitative image search results on CityFlow. We select the four query images from different viewpoints, *i.e.*, the front view, the overhead view, the rear view and the side view. The proposed method has successfully retrieved the relevant results in the top-5 of the ranking list.

Visualization of Learned Heatmap. Following [38], [61], we utilize the network activation before the pooling layer to visualize the attention of the learned model. As shown in Figure 7, the trained model has strong response values at the regions containing discriminative details, such as headlights and tire types. In particular, despite different viewpoints, the model could focus on the salient areas, yielding the viewpoint-invariant feature.

Model Convergence. As shown in Figure 8 (left), despite a large number of training classes, *i.e.*, 31,805 categories in VehicleNet, the model could converge within 60 epochs.

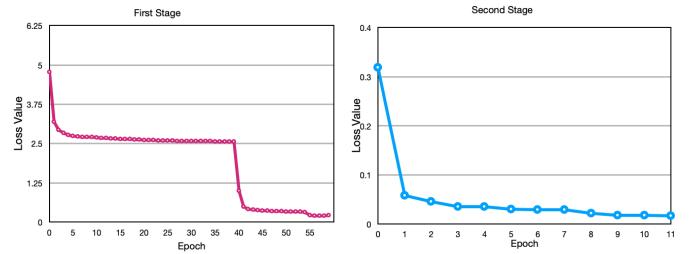

Fig. 8. The training losses of the two stages. Due to the large-scale data and classes, the first stage (left) takes more epochs to converge. Attribute to the trained weight of the first stage, the second stage (right) converge early.

Meanwhile, as discussed, the first stage provides a decent weight initialization for fine-tuning in the second stage. Therefore, the Stage-II training converges quickly within 12 epochs (see Figure 8 (right)).

VI. CONCLUSION

In this paper, we intend to address the two challenges in the context of vehicle re-identification, *i.e.*, the lack of training data, and how to harness the multiple public datasets. To address the data limitation, we build a large-scale dataset called VehicleNet with free vehicle training images from public datasets. To learn the robust feature, we propose a simple yet effective approach, called two-stage progressive learning, and discuss the advantages of the learning strategy.

To verify the effectiveness of the proposed pipeline, we have evaluated the method on the private test set of CityFlow [2] and achieved the competitive performance in the AICity19 Challenge. The proposed method has surpassed the champion of the challenge, yielding 86.07% mAP accuracy. Besides, the proposed method also has achieved competitive performance on two other public datasets, *i.e.*, VeRi-776 and VehicleID.

In this paper, we show that more training data matters, and could contribute to the learning of robust visual representation. However, the data collection is still challenging. In the future, we will investigate the synthetic data generated by either GAN [27] or 3D-models [62], to further explore the robust representation learning.

Yunchao Wei received his Ph.D. degree from Beijing Jiaotong University, Beijing, China. He was a Postdoctoral Researcher at Beckman Institute, UIUC, from 2017 to 2019. He is currently an Assistant Professor with the Centre for Artificial Intelligence, University of Technology Sydney. He is ARC Discovery Early Career Researcher Award (DECRA) Fellow from 2019 to 2021. His current research interests include computer vision and machine learning.

Yi Yang received the Ph.D. degree in computer science from Zhejiang University, Hangzhou, China, in 2010. He is currently an associate professor with University of Technology Sydney, Australia. He was a Post-Doctoral Research with the School of Computer Science, Carnegie Mellon University, Pittsburgh, PA, USA. His current research interest includes machine learning and its applications to multimedia content analysis and computer vision, such as multimedia indexing and retrieval, video analysis and video semantics understanding.

Zhedong Zheng received the B.S. degree in computer science from Fudan University, China, in 2016. He is currently a Ph.D. student with the School of Computer Science at University of Technology Sydney, Australia. His research interests include robust learning for image retrieval, generative learning for data augmentation, and unsupervised domain adaptation.

Tao Ruan received the B.E. degree in computer science and technology from Beijing Jiaotong University, Beijing, China, in 2016. He is currently a Ph.D. candidate with the Institute of Information Science, Beijing Jiaotong University, Beijing, China. His research interests include video synopsis and pixel understanding.

Tao Mei is a Technical Vice President with JD.com and the Deputy Managing Director of JD AI Research, where he also serves as the Director of Computer Vision and Multimedia Lab. Prior to joining JD.com in 2018, he was a Senior Research Manager with Microsoft Research Asia in Beijing, China. He has authored or coauthored over 200 publications (with 12 best paper awards) in journals and conferences, 10 book chapters, and edited five books. He holds over 50 US and international patents (20 granted). He is or has been an Editorial Board Member of IEEE Trans. on Image Processing, IEEE Trans. on Circuits and Systems for Video Technology, IEEE Trans. on Multimedia, ACM Trans. on Multimedia, Pattern Recognition, etc. Tao received B.E. and Ph.D. degrees from the University of Science and Technology of China, Hefei, China, in 2001 and 2006, respectively. He was elected as a Fellow of IEEE (2019), a Fellow of IAPR (2016), a Distinguished Scientist of ACM (2016), and a Distinguished Industry Speaker of IEEE Signal Processing Society (2017), for his contributions to large-scale multimedia analysis and applications.
